Results of the NY Starter Phosphorus Project’s “Phosphorus Survey for Corn Growers”

October 8, 2004

Sheryl N. Swink, Quirine Ketterings, Karl J. Czymmek

New York corn growers were surveyed between August 2003 and May 2004 to assess: 1) current phosphorus (P) starter fertilizer use for corn; 2) awareness of starter P research carried out over the past 3 years (the New York Starter Phosphorus Project funded by NESARE and others); and 3) the likelihood of growers reducing P application rates in the future. The actual survey is shown in Figure 1 and a summary of responses follows.

**Figure 1.** Postcard-style questionnaire used to survey New York corn producers.

**Phosphorus Survey for Corn Growers**

How many acres of corn do you grow? _____ acres  County: ________________________

Do you soil test your corn field(s) at least once every 3 years? ___ yes ___ no

What starter fertilizer blend do you use for corn? _____-_____-_____       ______ lbs/acre or ______ gals/acre

What starter blend did you use 5 years ago?    _____-_____-_____        ______ lbs/acre or ______ gals/acre

Did you know that NY research shows no yield response to P if soils test very high for P? ___ yes ___ no ___ heard about this but wasn’t sure

As a result of the information about the outcome of the NY Starter P trials, would you be more likely to soil test and change starter P rates? ____ yes ____ no

---

**How many farmers responded?**

Altogether, 379 surveys were filled out by producers representing 40 New York counties (there are 51 counties with significant corn production in New York as reported by the New York Agriculture Statistics Service1).

Three groups of producers were surveyed. The first group consisted of 75 corn growers (from 30 different counties) who visited the Cornell Nutrient Management Spear Program’s booth at Empire

---

Farm Days on August 5, 6, and 7, 2003. Another 274 corn growers (24 counties) filled out the survey at field crop extension meetings held during January, February and March of 2004 (see Appendix A). The third group consisted of 30 members of New York Corn Growers Association (18 counties) who returned survey postcards included with the Association’s newsletter in March of 2004. The three groups will be identified as “Empire Farm Days”, “2004 Winter Meetings”, and “NY Corn Growers Association”. Survey results will be presented for each of the groups individually and for all three groups combined.

Respondents did not always answer all of the questions, thus the data summarized below are based on the total number of responses to a particular question, not the total number of surveys cards turned in.

**How many corn acres are represented by the survey?**

The New York Agriculture Statistics Service estimated that 912,000 acres of corn (silage and grain) were grown in 2003 in the 40 counties represented in our survey. The 379 producers who responded to the survey jointly represented 86,803 acres of corn, almost 10% of the total corn acreage in the counties (Table 1).

There were differences among the groups of producers surveyed in terms of acreage of corn grown per farm (Table 1). The members of the New York Corn Growers Association that returned the survey mainly represented producers with large acreages of corn, averaging just over 500 corn acres per farm. Only 7% of this group reported growing less than 100 acres of corn and close to 70% cultivated more than 200 acres of corn. Those that filled out the surveys at the 2004 Winter Meetings tended to have smaller corn acreages with an average of just under 200 acres per farm. More than 40% of the producers from the 2004 Winter Meetings grew less than 100 acres of corn and only 25% grew more than 200 acres. The average corn acreage for the Empire Farm Days group was 265 acres per farm with a more equal distribution of corn acreage across the group; 37% reported growing less than 100 acres of corn and 37% reported growing more than 200 acres.

**How many corn growers had heard about the NY Starter Phosphorus Project and its findings?**

Thirty-six percent of those responding at Empire Farm Days indicated they knew about the project’s major findings. Another 22% had “heard” about the project but were not sure about the details, while 42% had not heard about the project at all prior to meeting us at the 2003 Empire Farm Days (Table 2). The survey at Empire Farm Days in 2003 took place after two years of field trials and the
distribution of two extension articles with preliminary findings, but before broader dissemination of results derived from the full three-year dataset.

In January of 2004, results from the three years of research were summarized and reported to extension educators, farmers, and crop consultants through articles in various media and at meetings. Following these outreach events, the survey was distributed by County Extension Educators at a number of Field Crop meetings in early 2004 and in a May 2004 mailing to members of the New York Corn Growers Association. Responses in these later surveys (Table 2) suggest increasing awareness over time due to greater penetration by extension outreach once the 3 year study was completed and more formally promoted: 72% (Winter Meetings) and 90% (New York Corn Growers Association) responded that they either knew about the outcomes of the project (50-63%) or that they had heard that work was being done but were not sure about the details (22-27%).

Have producers reduced their use of starter phosphorus in the past 5 years?

Five years ago, 17% of the producers applied 0-25 lbs P₂O₅ per acre with starter fertilizer (Table 3). This is the recommended rate for soils testing high to very high in P in New York. According to the survey responses, the percentage of producers using 0-25 lbs P₂O₅/acre nearly doubled over the life of the New York Starter Phosphorus Project (currently 33% of the producers in the survey applying 0-25 lbs P₂O₅ per acre). Forty-one percent of respondents reduced P application rates while 17% increased applications (perhaps due to soil testing), resulting in a decrease in the average application rate from about 44 lbs per acre five years ago to 37 lbs P₂O₅ per acre in 2003. In 2003, a combined total of 377 tons less P₂O₅ was used than 5 years ago on the almost 30,000 acres of corn fields planted by respondents who reduced their rates of application (Table 4).

For the group of producers represented in the 2004 Winter Meetings and the New York Corn Growers Association, reductions in P starter use mainly occurred on farms whose application rates were less than 70 lbs P₂O₅ per acre (the equivalent of P removal by an average corn crop). The percentage of producers that applied more than 70 lbs of P₂O₅ per acre remained fairly constant over time (11% five years ago and 9% currently). The New York Corn Growers Association members responding to the survey, on average, apply more P fertilizer to corn (42 lbs P₂O₅ per acre) than the producers surveyed at the extension winter meetings (36 lbs of P₂O₅ per acre). However, there is insufficient information (no soil test P or manure application data) to determine whether or not the two groups differ in starter P use relative to soil test P values. The vast majority of the members of the NY Corn Growers Association, about 90%, are cash cropping corn² and most likely not

² Personal communication with Ann Peck, Executive Secretary of the New York Corn Growers Association (this is a rough estimate as the Association has not actually collected this kind of information from its members).
spreading manure (an important source of P on many farms) like the dairy farmers who produce forage and grain corn for their herds. Due to this, many of the Association respondents' corn fields are expected to have lower soil test P levels and therefore require greater applications of starter P for optimum yield.

Table 3. Changes in starter phosphorus applications since initiation of the NY Starter P Project.

Fifty percent of the corn producers that knew about the project and its findings reduced the amount of P starter fertilizer as compared to rates used five years ago (Table 5). In addition, of those who indicated familiarity with the project but still used the same amount of P starter fertilizer as five years ago, a large proportion (38%) were already applying P at low rates (0-25 lbs P_2O_5/acre).

To assess the impact of the project, we need to compare the percentage of people that knew about the project (50%, Table 5) and reduced P starter use in the past five years with the percentage of people that reduced rates without knowing about the project. Of those that were unfamiliar with the project, 32% reduced starter P use (Table 6). Assuming that an equivalent percentage of the
respondents who knew about the project would have reduced rates regardless (i.e., 32% of the 134 “yes” responses in Table 5), the survey indicates that the New York Starter P Project convinced at least 18% or about 1 in 5 of the producers who heard about the research to reduce P starter use during the trial phase. It should be noted that five years ago, prior to the project, 17% of all producers surveyed were already applying starter P within the recommended range of 0-25 P₂O₅ lbs/acre for high to very high testing soils (Table 3) and that others may have soils that test low or medium for P (currently 47% of New York soils tested through the Cornell Nutrient Analyses Laboratory test low or medium in P).

Table 5. Relationship between starter P knowledge and change in application rates: responses from producers that knew NY research had shown no yield response to P if soils test very high for P.

Do we expect further changes in the future?
Lack of awareness and lack of soil test P information may be holding many producers back from making reductions. More than 80% of producers that heard about the project and its findings indicated that they are now likely to soil test regularly and change starter P rates as a result the project (Table 7). In addition, a large percentage of those producers who had little or no familiarity with the project prior to exposure at the time they received the survey indicated an increased willingness to change P starter management. Twenty-eight percent of all survey respondents indicated that they did not soil test regularly (at least once every 3 years). It is expected that many of these producers and others who are becoming aware of the results of the New York Starter Phosphorus Project due to greater extension outreach since completion of the study will now have their soil tested and make changes to their application rates based on the results.

So, do we expect further changes in the future? Yes! It is expected from the results of this survey that at least 18-50% of those newly aware of the New York Starter P Project results will make some reduction in their application of starter P based on this awareness, levels of manure use and the results of soil tests. Just how much more change occurs will likely depend on the ease and
economics of applying different starter blends and/or adjusting rates for fields with different P levels.

**Summary and Conclusions**

During the past few years, 71% of the producers surveyed had heard about the New York Starter P Project. Fifty percent of these producers reduced P starter use over the past five years as compared to 32% of those who had no knowledge of the project. Current application rates across all farms averaged from 36 lbs P₂O₅ per acre for those that attended extension events in the winter of 2004 to 42 lbs P₂O₅ for members of the New York Corn Grower Association. Among those surveyed, 77 to 86% indicated they were more likely to soil test on a regular basis and to change rates if needed, hence further changes in starter P use are expected in the future.

More detailed surveys will be conducted among producers and field crops extension educators that participated in the project during the fall and winter of 2004. Final survey results will be compiled and presented in the spring of 2005.

**For Further Information**

For further information contact your local Cornell Cooperative Extension office, contact Quirine M. Ketterings at (607) 255 3061 or qmk2@cornell.edu, and/or visit the New York Starter Phosphorus Project website: http://nmsp.css.cornell.edu/projects/starterp.asp.
