Whole Farm Evaluation

Howland Dairy Benefits from Whole Farm Analysis Project

By Lisa Fields

The Whole Farm Nutrient Analysis Program (WFA) came along at the right time for Rob Howland of Candor, NY. Howland’s 74 cow dairy is one of eleven farms in the WFA project, an initiative of Cornell’s Nutrient Management Spear Program (NMSP). The WFA identifies opportunities for change in nutrient inputs or allocations that could benefit the environment and the farm’s bottom line. The nutrient efficiency of a farm’s component areas are measured and analyzed with an integrated approach.

Howland described his reaction when approached by his Extension Field Crops Specialist, Janice Degni to participate in the project. “I immediately said that I would. I was aware of the concerns in society about the environment, and as a dairy farmer, business economics are always a personal concern. This farm has a fairly large land base, and I was questioning where in the crop system I would get the best return from my time and dollars.”

There are several stand-alone tools used to evaluate a farm’s nutrient status that tend to analyze a particular sector of the farm. An objective of the WFA project is to combine those tools and extract the data that are most essential for assessing nutrient status and providing valuable information to the farmer.

Patty Ristow, Extension Associate with the NMSP, explained the WFA process, “The first step is to compile accurate and relevant information to analyze the farm’s nutrient status. On the field side this consists of three key tools: a Whole Farm Nutrient Mass Balance (NMB), soil fertility analysis of all the fields, and nitrogen measures termed adaptive N management in corn fields.”

The NMB provides a mechanism for tracking nutrient use efficiency across the whole farm year after year. The analysis covers four farm production sectors: milk, animals, crops and feed. The NMB diagnostic reports quantify the net major nutrients that remain after subtracting nutrients exported from those imported to the farm.

The year-end data summary requires routine record-keeping for each production sector. That can make it challenging to complete, but Ristow noted that its role is crucial. “The NMB diagnostics have helped illustrate to farm management teams and environmental regulators that our farms’ management changes are greatly reducing the amount of nutrients that could affect water resources. By tracking changes over time a powerful message is delivered from the whole farm perspective.”

Howland commented further, “At first I didn’t find the NMB to be useful. Getting the data together was tough, because it didn’t fit with my record keeping system. After about two years I made some adjustments in tracking forage inventory, and that’s helped both the NMB data needs and my feed system. I started tracking my baleage more specifically as to time of cutting and the field it came from.”
management tools for nitrogen in corn fields. The Illinois Soil Nitrogen Test (ISNT) can be taken prior to crop planting and predicts the soil’s ability to supply N to the crop by determining the amount available to mobilize from the pool of organic N. The Corn Stalk Nitrate Test (CSNT) is a nitrate analysis of the bottom portion of the corn stalks at harvest time. It tells the story of how the prediction of N supply and use of fertilizer and/or manure played out in reality. These two tools together allow for fine-tuning of N applications over time and on a field by field basis.

Looking to the future, the program hopes to integrate economic measures from Cornell’s Dairy Farm Business Summary into the WFA diagnostics, identifying factors of profitability that correlate with nutrient efficiency. This could provide financial documentation to the benefits seen by WFA participants. Ristow commented: “The changes made as a result of tracking the NMB and fine-tuning nutrient distribution and nitrogen use on corn often result in reduced purchases and alleviate excessive nutrient levels that may affect water resources. It’s a win-win scenario for the farm’s economics and the environment."

Howland summarized his opinion of the WFA project.” Participating in this type of project raises your level of consciousness as it puts the farm’s nutrient use facts in front of you. If something looks high, you have the tools to consider how to change that.” Noting the fit between the WFA project and his business philosophy, he added, “It’s important to know what the issues are that can affect your business. You can’t farm in a vacuum.”

To learn about and participate in the statewide whole farm nutrient mass balance project, check out the NMB website of the Cornell Nutrient Management Spear Program: http://nmsp.cals.cornell.edu/projects/massbalance.html.

The Nutrient Management Spear Program (N MSP) is an applied research, teaching and extension program for field crop fertilizer and manure management on dairy and livestock farms. It is a collaboration among faculty, staff and students in the Department of Animal Science, Cornell Cooperative Extension, and PRO-DAIRY. Our vision is to assess current knowledge, identify research and educational needs, facilitate new research, technology and knowledge transfer, and aid in the on-farm implementation of strategies for field crop nutrient management including timely application of organic and inorganic nutrient sources to improve farm profitability while protecting the environment. An integrated network approach is used to address research, extension and teaching priorities in nutrient management in New York State. For more information on N MSP projects and extension/teaching activities, visit the program website (http://nmsp.cals.cornell.edu) or contact Quirine Ketterings at qmk2@cornell.edu or (607) 255-3061.
